

Visualization Literacy Analysis

Derek Harter, Shulan Lu

11/12/2025

Read in data files

Raw data is in the ../AccData subdirectory in two excel spreadsheet files per participant. The following code combines into single dataframe of all data.

```
#grab files from google drive (only have to do this once)
# source("getFromGoogleDrive.R")

#get the first 6? characters of each data file
#get unique values of these
# this is list of subject ids

raw_file_names <- list.files("../AccData")
first_six <- substr(raw_file_names, 1, 6)
sub_ids <- unique(first_six)

# fast_RT = data.frame(ParticipantId = character(),
#                        TrialName = character(),
#                        type = character(),
#                        time = numeric()
# )

all_data <- NULL

for (i in 1:length(sub_ids)){

  if (grepl("~$", sub_ids[i], fixed = T)){
    next
  }

  temp_file1 <- read_xlsx(paste0("../AccData/", sub_ids[i], "_1.xlsx")) %>%
    slice(1:17) %>%
    select(-starts_with("Order")) %>%
    rename(correct = 8)

  temp_file2 <- read_xlsx(paste0("../AccData/", sub_ids[i], "_2.xlsx")) %>%
    slice(1:17) %>%
    select(-starts_with("Order")) %>%
    rename(correct = 8)

  new_temp <- temp_file1 %>%
    bind_cols(temp_file2$correct) %>%
```

```

  rename(Correct_1 = correct, Correct_2 = "...9") %>%
  mutate(AnswerRT = TimeToBeginInput - TimeToReadQuestion)

all_data <- all_data %>%
  bind_rows(new_temp)
}

all_data <- all_data %>%
  rename(readRT = TimeToReadQuestion, totalRT = TimeToBeginInput)

#read in trialtype key (I created this from an early version of the previous paper)
trial_type_key <- read.csv("../trial_type_key.csv", stringsAsFactors = F)

all_data <- all_data %>%
  mutate(TrialType = trial_type_key$TrialType[match(TrialName, trial_type_key$TrialName)]) %>%
  mutate(TrialType = paste0("Type", TrialType))

# remove temporary dataframes to keep workspace cleaner as we go forward
rm(new_temp)
rm(temp_file1)
rm(temp_file2)
rm(trial_type_key)

```

Basic checks

Just a sanity check of all the data. Summary of number of subjects in each of the 3 condition types.

```

#how many participants per condition
all_data %>%
  group_by(ParticipantId, Condition) %>%
  summarize(ntrials = n()) %>%
  group_by(Condition) %>%
  summarize(nsubs = n()) %>%
  summary()

```

`summarise()` has grouped output by 'ParticipantId'. You can override using the `.groups` argument.

```

##   Condition      nsubs
## Length:3      Min.   :33.00
## Class :character 1st Qu.:36.00
## Mode  :character Median :39.00
##                Mean   :40.67
##                3rd Qu.:44.50
##                Max.   :50.00

```

#why is the balance so off?

Remove outliers based on RT

Removing outliers, resulting in data frame named `all_data_no_outliers`.

1. All trials where the **AnswerRT** is less than 2 seconds are removed first, which assumes these reactions were too fast so were done without an actual considered response.
2. All trials where the **AnswerRT** is 3 standard deviations different from the mean are removed next.

Table shows summary of mean and standard deviation of answer RT by each of the trial question types, as well as the 3 standard deviation upper and lower bound of the reaction time.

Displayed histogram is a sanity check of the number of trials each participant in all of the data have done. Most participants should do 16 trials. Less than that are from dropped data for outliers.

```
#removing on trial-by-trial basis

#remove answerRTs below 2000ms first
all_data_remove <- all_data %>%
  filter(AnswerRT >= 2000)
dim(all_data)[1]

## [1] 2074
dim(all_data_remove)[1]

## [1] 2067
#drops 7 trials

# also remove AnswerRT that are more than 3 standard deviations away from
# the mean
all_data_no_outliers <- all_data_remove %>%
  group_by(TrialName) %>%
  filter(!(abs(AnswerRT - mean(AnswerRT)) > 3.0*sd(AnswerRT)))
dim(all_data_no_outliers)[1]

## [1] 2020
#drops 47 more trials

rt_data_summary <- all_data_no_outliers %>%
  group_by(TrialName) %>%

```

Extract Only One Type of Chart

Create a dataframe from the data with no outliers that contains only XChartQ1 through XChartQ4 trials for the following analysis.

We replace the `all_data_no_outliers` dataframe with one containing only the selected TrialName question type here, so past this point we are analyzing only this particular TrialName type.

We show the table again of the mean RT for this question type. The table should match the one done with all of the data, but we should only have the particular question trial name type now in the data.

We also again plot the histogram of the number of trials. Participants should have seen 4 of each particular question type, but after removing outliers some only have 3, 2 or 1 remaining.

```
all_data_no_outliers <- all_data_no_outliers %>%
  filter(grepl("BarChartQ[0-9]", TrialName))

rt_data_summary <- all_data_no_outliers %>%
  group_by(TrialName) %>%
  summarize(meanAnswerRT = mean(AnswerRT, na.rm = T),
            sdAnswerRT = sd(AnswerRT, na.rm = T),
            LB = meanAnswerRT - 3*sdAnswerRT,
```

```

UB = meanAnswerRT + 3*sdAnswerRT
summary(rt_data_summary)

##   TrialName      meanAnswerRT    sdAnswerRT      LB      UB

Alternative Analysis using glmm TMB package

The following analysis is for the heterogenous group condition analysis. See .

The following determines if a more complex model is justified.

```
model_glmm_hom = glmmTMB(mean_answerRT ~ Condition * TrialType + (1 | ParticipantId),
                          data=trial_type_means, family = Gamma(link="log"),
                          dispformula = ~ 1, REML = FALSE)
model_glmm_hetero = glmmTMB(mean_answerRT ~ Condition * TrialType + (1 | ParticipantId),
                             data=trial_type_means, family = Gamma(link="log"),
                             dispformula = ~ Condition, REML = FALSE)

anova(model_glmm_hom, model_glmm_hetero)
```

```
## Data: trial_type_means
```

```
## Models:
```

```
## model_glmm_hom: mean_answerRT ~ Condition * TrialType + (1 | ParticipantId), zi=~0, disp=~1
```

```
## model_glmm_hetero: mean_answerRT ~ Condition * TrialType + (1 | ParticipantId), zi=~0, disp=~Condition
```

```
##           Df    AIC    BIC logLik deviance Chisq Chi Df Pr(>Chisq)
```

```
## model_glmm_hom      11 7517.9 7560.6 -3747.9   7495.9
```

```
## model_glmm_hetero  13 7521.4 7571.9 -3747.7   7495.4 0.4736      2    0.7892
```

Try overall effect reporting

```

Compare Accuracy

Extract wide dataframe

Do all of the previous again but on the Accuracy results.

We again create a dataframe in needed format of only the accuracy data.

A bit different from before, only need to create an average of the two correct features we have. But then we do a similar transformation into wide format and replace na/missing values.

```
all_data_no_outliers <- all_data_no_outliers %>%  
  rowwise() %>%  
  mutate(Correct_Avg = mean(c(Correct_1, Correct_2)))
```

```
trial_type_mean_accuracy <- all_data_no_outliers %>%  
  group_by(ParticipantId, Condition, TrialType) %>%  
  summarize(mean_acc = mean(Correct_Avg),  
            n = n())
```

`summarise()` has grouped output by 'ParticipantId', 'Condition'. You can override using
the `.groups` argument.

```
#rm(trial_type_mean_accuracy)
```

```
# Step 1: Aggregate to the Participant Level  
# In a mixed design, the experimental unit is the Participant.  
# We first average all raw trials for each person within each Trial Type.
```

```
subject_means <- all_data_no_outliers %>%  
  group_by(ParticipantId, Condition, TrialType) %>%  
  summarize(  
    subject_avg = mean(Correct_Avg, na.rm = TRUE),  
    .groups = "drop"  
  )
```

```
# Step 2: Compute Descriptive Stats for the Groups  
# Now we calculate the stats across participants.
```

```
descriptive_stats <- subject_means %>%
